DATA REPOSITORY

In this data repository, we present description of apatite fission track (AFT) samples (Table DR1), summary fission track age (Table DR2), summary fission track length (Table DR3), single-grain fission track age data (Table DR4), complete track-length measurements (Table DR5), apatite (U-Th)/He data (Table DR6), and geothermal gradient calculations using bottom-hole temperature measurements (Table DR7). Additionally, we present a brief description of the analytical methods used for apatite (U-Th)/He thermochronology.

APATITE (U-TH)/HE THERMOCHRONOLOGY METHODS

Apatites were handpicked and photographed under a polarizing Leica MZ16 stereographic microscope. All grains were examined under transmitted light (plane polarized and cross polarized) and reflected light while submerged in ethyl alcohol to screen for optically visible inclusions and to identify euhedral, unfrosted, and unfractured grains. Generally, an attempt was made to pick five grains per sample; however, the low sample yields from the borehole cuttings often prevented this. Grain dimensions were measured in order to calculate α -ejection corrections for each grain.

Apatites were sealed in niobium tubes and loaded into a copper planchette. Helium (He) concentration was measured by ^3He isotope dilution using a Balzers QMS 200 quadrupole mass spectrometer at the University of California at Santa Cruz. Apatite grains were degassed at approximately 1000°C (~1832°F) for 3 min. Grains were then analyzed with a second

extraction, as a way to detect incomplete degassing, possibly related to He from more retentive phases included within the crystal. After He measurements, apatites were spiked using a mixed ^{229}Th - ^{233}U tracer. Apatites were dissolved in concentrated HNO_3 and zircons were dissolved in HF and HNO_3 for isotopedilution inductively coupled plasma mass spectrometry (ICP-MS) analysis of U and Th isotopes, on a Thermo Scientific X-series II quadrupole ICP-MS at the University of California at Santa Cruz. Three fragments of Durango fluorapatite standard were analyzed along with the apatites.

Ages were corrected for α -ejection using the procedures of Farley et al. (1996).

*calculated using polynomial equation from Farley (2002) and average measured grain width and length

**Effective Ft from Ketcham et al. (2011), Ft for grains with Req < 30 μm from Farley et al. (1996); all corrections assume stopping distances from Ketcham et al. (2011)

***assumed 6% 2 standard deviation uncertainties on single grain ages, based on Durango apatite reproducibility, which is larger than propagated analytical uncertainties

¹maximum measured bottom hole temperature at given depth

²bottom hole temperature (BHT) calculated using Horner plot technique, only for intervals with time series of BHT measurements

³Tmax for intervals with a single BHT measurement, Teq for intervals with a time series of BHT measurements

⁴geothermal gradients in units of °C/km, seafloor temperature of 2°C is assumed
